ABSTRACT OF THE DISCLOSURE

A system which processes special characters used in a dynamic document in real time to make them viewable at a remote computer system. A special character image management unit is employed in a general purpose computer to manage the special characters used in its database. Inside this management unit, a special character definition unit determines which special characters to into graphic images, thus creating a special character database file. Graphic images of those special characters are produced by a special character character pattern based a dictionary generator, on containing character patterns. The produced special character image files form a special character dictionary, which is transferred to a document conversion server machine, together with the character database file. Using the special character database file, a special character identification unit identifies special characters used in a given source document, while a font size tracking unit keeps track of the current font size in the document. For each special appearing in the source document, character link generator produces a link to a relevant file. Finally, a compilation unit generates an output file, replacing every special character with a link to corresponding image file.
